Impact of Tidal-stream Energy Converter (TEC) arrays in relation to the natural variability of sedimentary processes

PRIFYSGOL BANGOR UNIVERSITY

Peter E. Robins p.robins@bangor.ac.uk
Simon P. Neill s.p.neill@bangor.ac.uk
Matt J. Lewis m.j.lewis@bangor.ac.uk

Case study: Northwest Anglesey, UK

- One of 7 UK regions of interest for 'first generation' energy extraction
- Skerries leased from the Crown Estate for commercial development by MCT

Why?

- Tidal velocities > 2.5 m/s
- Water depths = 30 m
- Distance to shore < 5 km
- Holyhead harbour nearby
- National grid connection

Sedimentary impacts:

Suspended sediment
- Turbidity maxima

bedload sediment
- Sand bank formation
- Net sediment transport fluxes

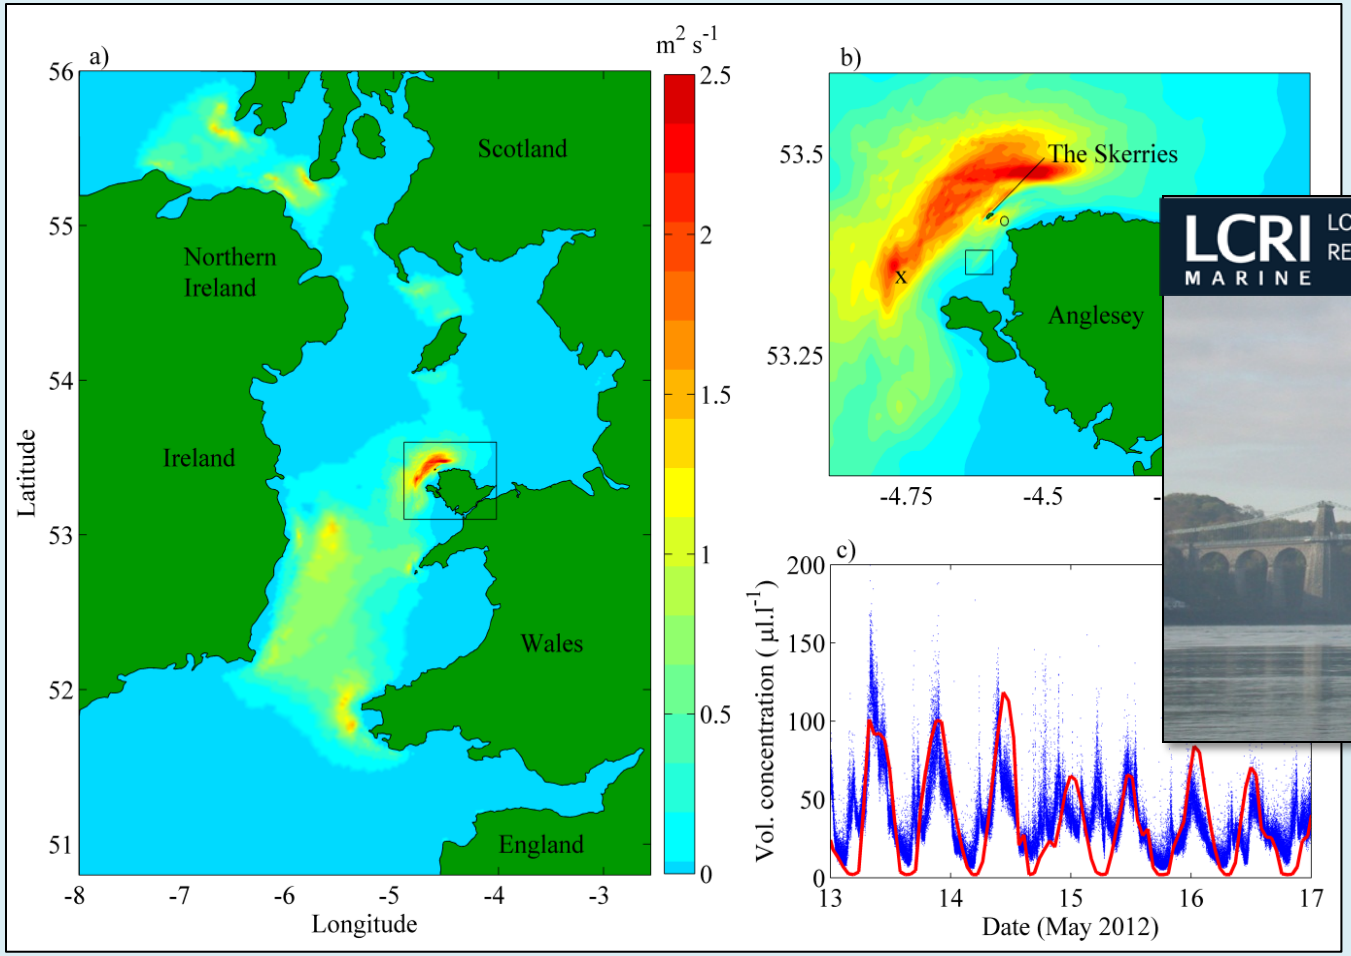
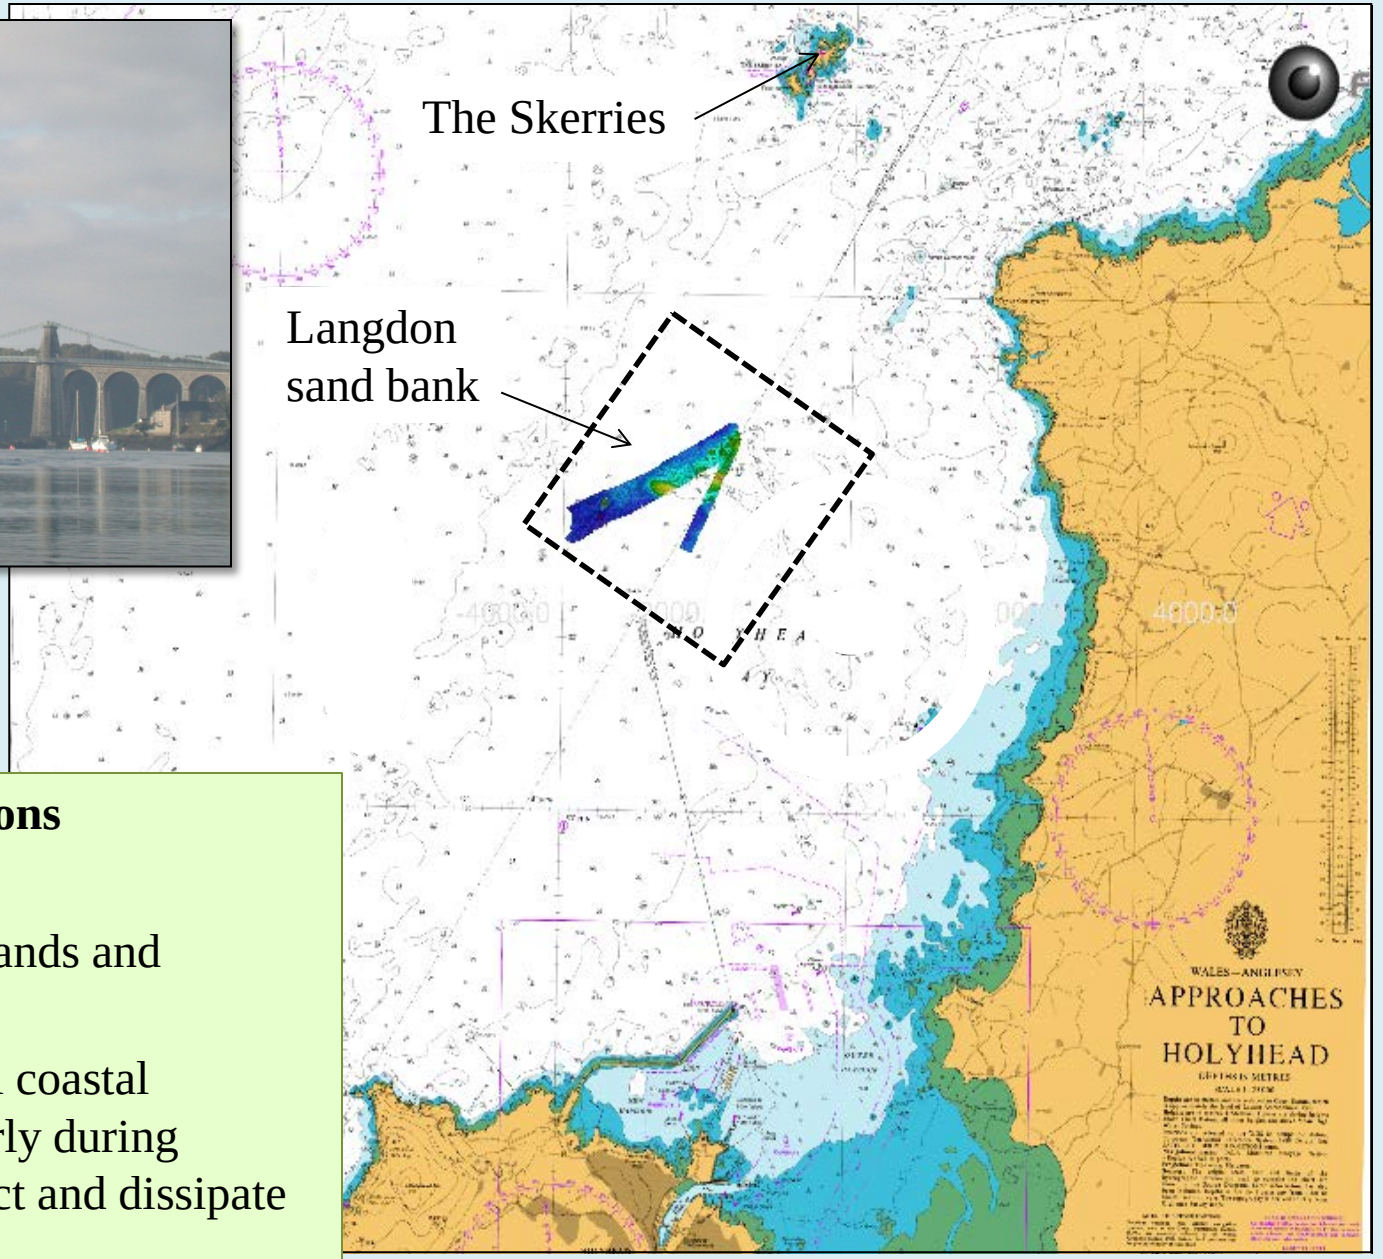
Why are sediment dynamics important?

1) **High tidal dissipation** ⇨ **Suspended sediment**: Anglesey turbidity maximum

- Enhance nutrient supply for marine species
- Increase secondary production
- Serve as critical nursery areas for economically important species





2) Sand bank formations

- form in the lee of islands and headlands
- Important for natural coastal protection, particularly during storms, as they refract and dissipate wave energy

3) Net bed load transport

Pingree and Griffiths (1979):

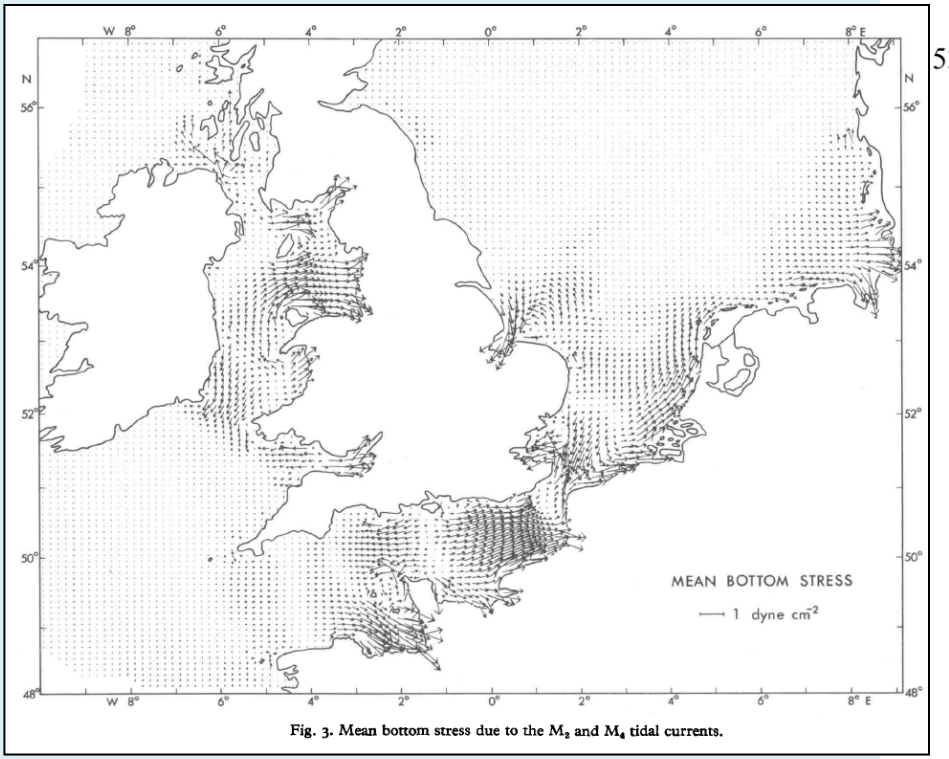

Fig. 3. Mean bottom stress due to the M_2 and M_4 tidal currents.

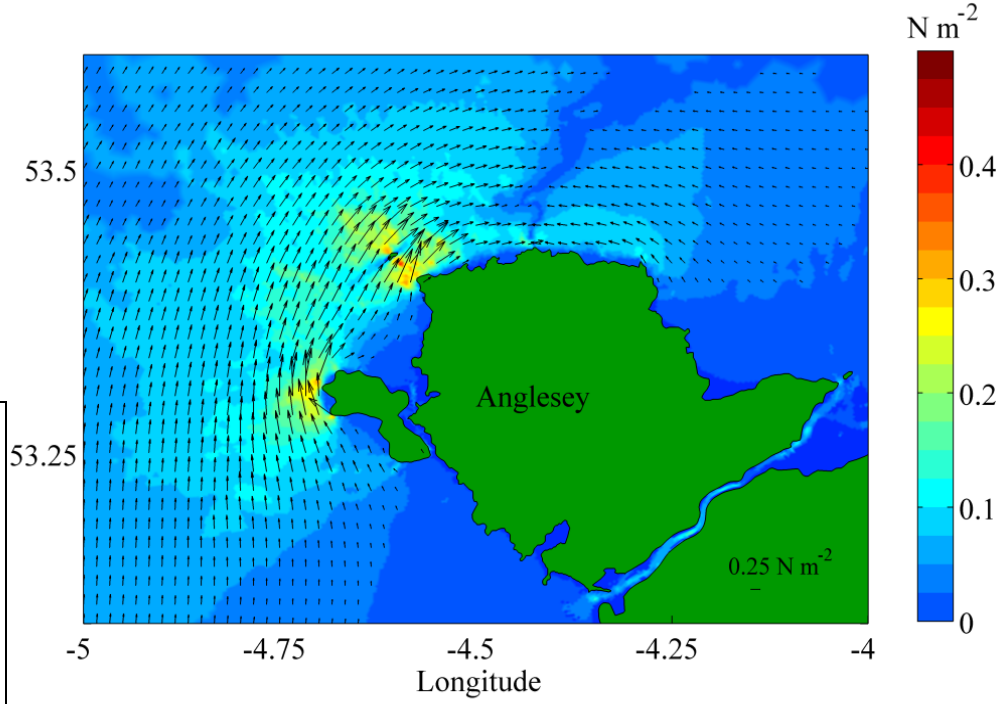
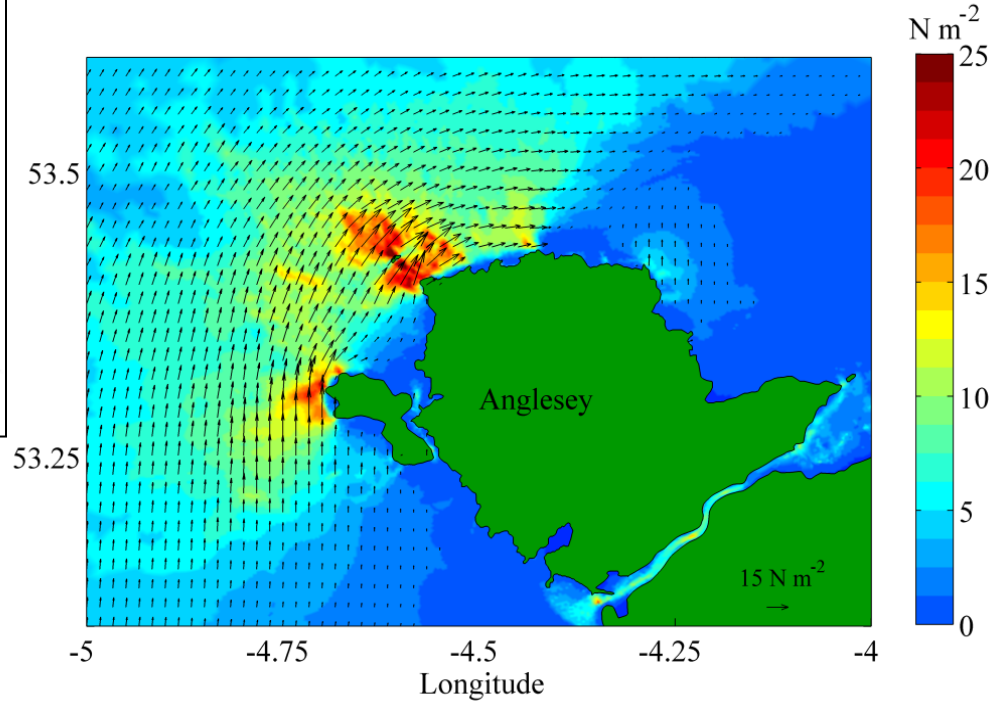




Natural variability: wave-induced bed shear stress

$$\tau_{wave} = \frac{1}{2}\,\rho\, f_w\, UW_{RMS}{}^2$$

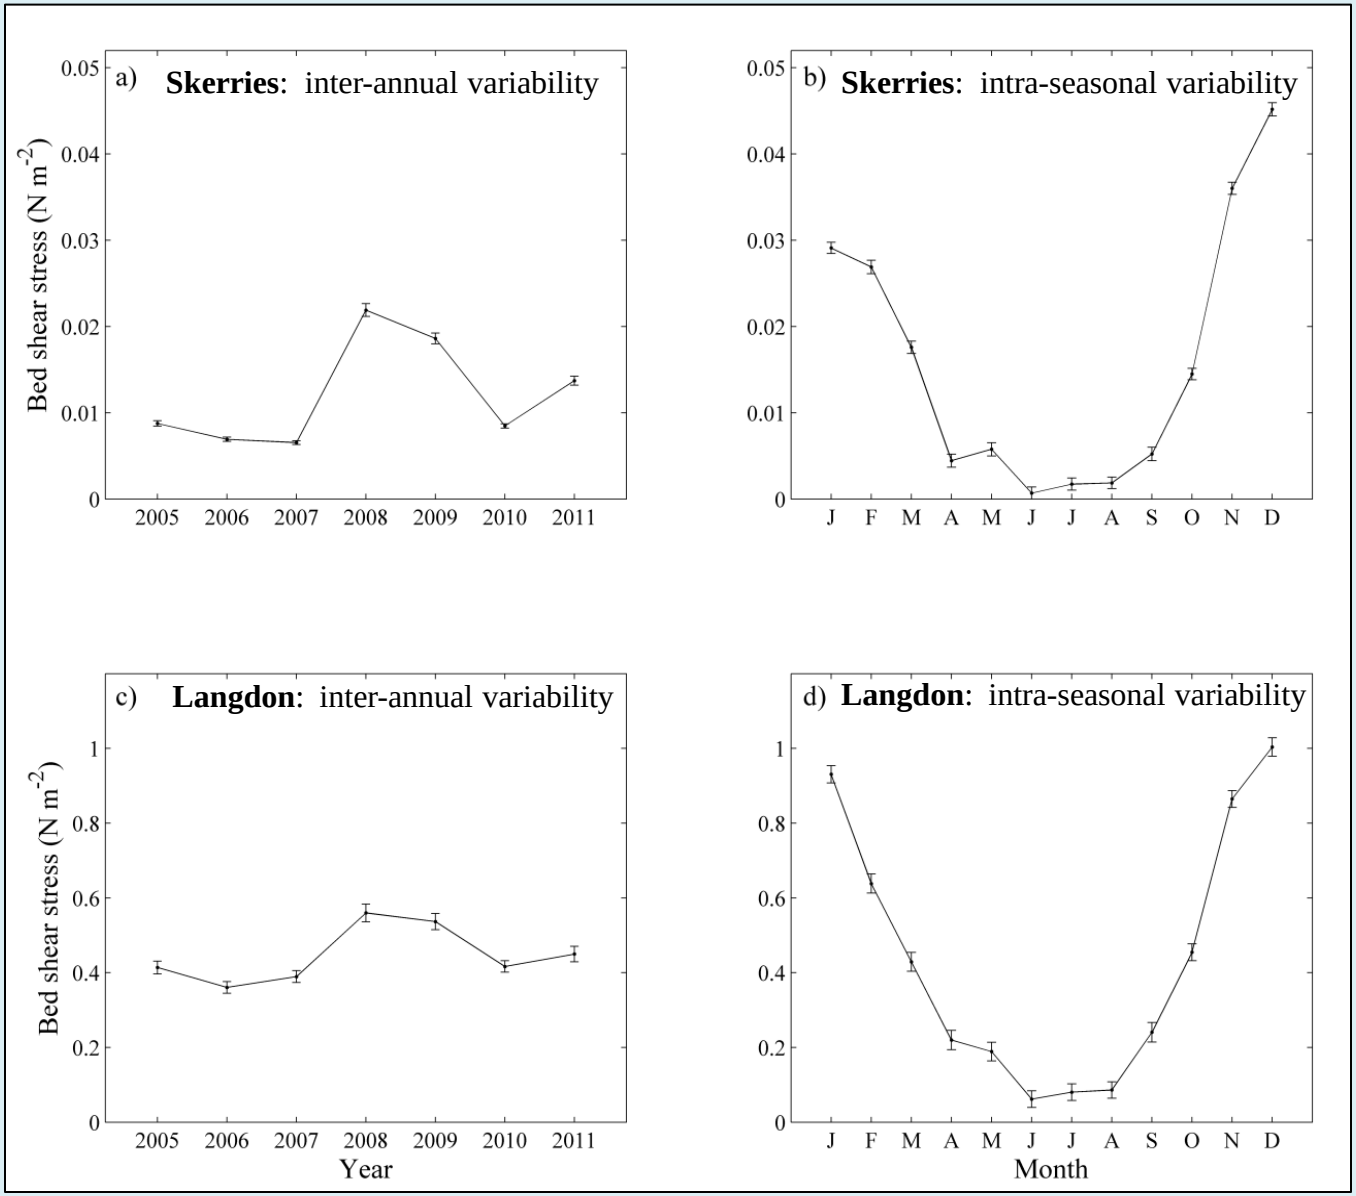
SWAN

- Spectral wave model
- NW European shelf
- 1/24° resolution
- Neill & Hashemi (2013)

RESULTS

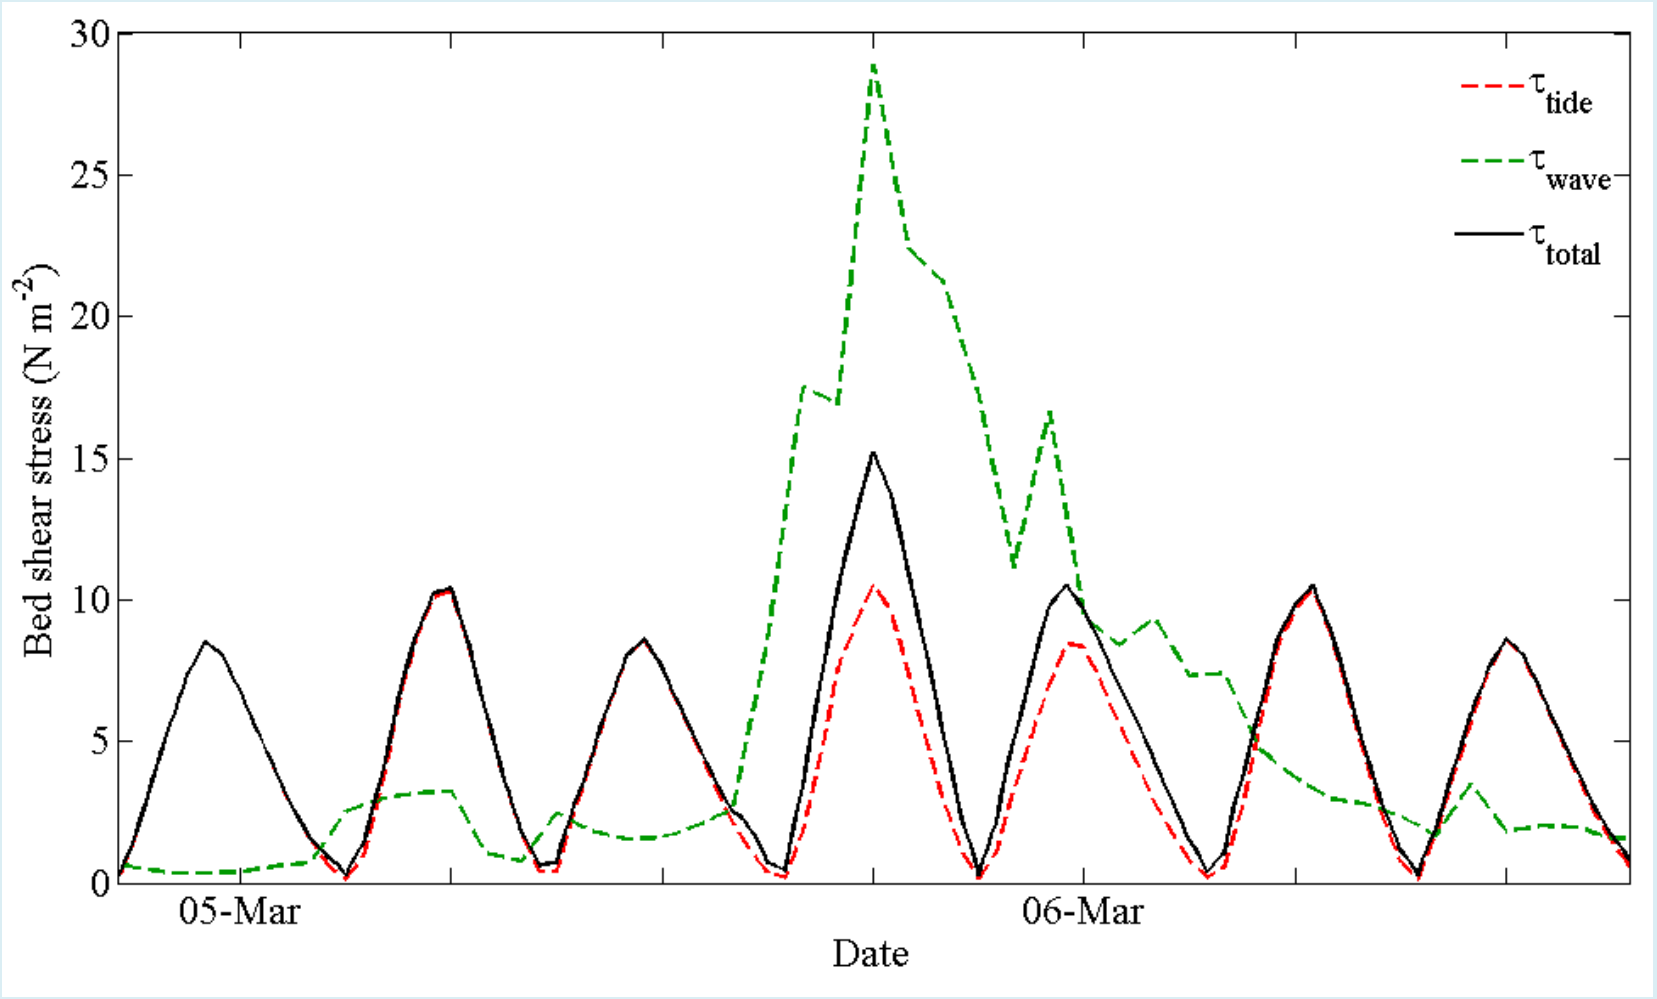
Skerries:
inter-annual: 0.012 ± 0.005
Intra-seasonal:
-Summer: 0.004 ± 0.002
-Winter: 0.03 ± 0.01

Langdon sand bank:
inter-annual: 0.45 ± 0.05
Intra-seasonal:
-Summer: 0.15 ± 0.06
-Winter: 0.72 ± 0.2



Combined stress: waves + tides

Soulsby (1997): $$\tau_{total} = \tau_{tide}\left[1 + 1.2\left(\frac{\tau_{wave}}{\tau_{tide} + \tau_{wave}}\right)^{3.2}\right]$$



Tidal-stream energy extraction

How do TEC arrays affect:

- Suspended sediment?
- Formation of sand banks?
- Net sediment fluxes?

Is the impact significant relative to natural intra-seasonal and inter-annual variations?

TEC array simulations:

- Turbines induce drag force on flow

$$F_x = -C_p \frac{P}{\rho U A D} cos(\theta)$$

- TEC array rated power modelled:
- 10, 50, 100, 300, 500 MW

Conclusions

- Telemac-2D Model simulated:
  - Anglesey turbidity maximum
  - net bed shear stress
  - sand banks formation

- First generation TEC arrays (10-50 MW) reduce velocities and bed shear stress by a few per cent, which could be considered insignificant compared to the natural variability.

- Further afield (10 km away), energy extraction did not exceed natural levels of variability in bed shear stress. However, this impact will always be site-specific.

- Sedimentary impacts of energy extraction should be considered at site selection stage.
